

# PROJECT SCHEDULE

Last updated: October 4, 2016

Week Ending	Phase	Primary Task	Subtasks	Status
07-Oct-16	Development	<b>A</b> Finalize Specification for proof of concept	1. Clarify the contents/scope of this specification. What does <i>this specific specification</i> require? (i.e., Audience, purpose, level of detail, technical vs functional)	Delayed
			2. Complete the specification.	Delayed
			3. Submit to group members for final revisions and editing.	Delayed
		<b>B</b> Finalize selection of sensors and start technical reports on assigned sensors	Pending...	Delayed
		<b>C</b> Familiarize group with Raspberry Pi development environment	1. Boot up the Raspberry Pi and spend an hour exploring the environment.	Completed
			2. Write some test code. Something that may be useful to the project eventually would be nice (ex., USB or Wi-Fi	On Schedule
			3. Give a tour of the OS to the other group members. Explain the example code functionality.	On Schedule
		<b>D</b> Get encoders working	1. Resurrect required resources from last semester and create a new project for testing the encoder software independently of the project.	Completed
			2. Write code that counts encoder veins while the wheels are spinning	Completed
			3. Write code that uses the counted encoder veins to determine speed and position of robot	On Schedule
			4. Integrate the independently validated encoder control software with the project code.	On Schedule

			5. Test that functionality of the encoders is still correct <i>and that no other functionality has been impaired by the integration.</i>	On Schedule
		<b>E</b> Choose the Supervisory control method	1. Experiment with the console in the Linux environment. Create code to gauge the level of complexity of tracking of keystrokes, including keys held and released, and any associated delays. 2. Create a list of pros/cons for each of the methods available (Joystick, Scripts or Keyboard).  3. Present findings to the group and make a final decision on the control method.	Completed  On Schedule  On Schedule
		<b>F</b> Finish COTS selection matrix	1. Gather power requirements of the Linux box (i.e., must power the camera, etc) 2. Finalize document, including any last requirements (power requirements from above) and associated analysis of possible solutions. 3. Present findings to the group and purchase/secure the selected COTS Linux box.	Completed  Completed  Completed
14-Oct-16	Design	<b>A</b> Get PID control working on the robot platform	1. Ensure encoders working with engineering units 2. Determine method of importing PID control into the system (writing code manually, using SimuLink) 3. Test and adjust PID control on the robot in an individual project. 4. Integrate with the main project code.	Pending  Pending  Pending  Pending
		<b>B</b> Prepare Raspberry Pi for Wi-Fi connection	1. Get Raspbian OS onto the raspberry Pi 2. Install Eclipse and C/C++ extension	Pending  Pending

		3. Check Wi-Fi internet connection on the Pi	Pending
<b>C</b>	Begin adjusting supervisory Linux program to work with the selected control method (i.e., Joystick...)	1. Prepare a new communication protocol based on the selected control method. 2. Implement the new communication protocol into the existing program.	Pending Pending
<b>D</b>	Initialize RS-232 on the Pi and get communication between it and the platform controller working.	1. Identify the name of the device (i.e. <code>/dev/tty__</code> ), using the USB-DB9 converter.  2. Decide on one of two options: (a) write a new program to communicate with the port, or (b) try to recycle the Linux Supervisor port communication code to work on the Pi. 3. Using a loopback connector from semester 3, write code to communicate with the port.  4. Integrate with the platform controller: ensure reliable communications between the modules.	Pending Pending Pending Pending
<b>E</b>	Investigate the need for threading in the supervisory Linux program	1. Create a pros/cons list of threading vs single thread program. Is the response of the system significantly affected if we only use a single thread?  2. If threading is deemed favourable or necessary, begin implementing threading. Ask Peter for a re-cap (or go back to old notes) on the common pitfalls and mistakes made	Pending Pending
21-Oct-16	Design	<b>A</b> Establish a reliable communication link between the Supervisory control program and the Raspberry Pi over Wi-Fi.	Pending Pending Pending

			4. Using socket communication send and echo back a single char	Pending
			5. Send and echo back strings	Pending
		<b>B</b>	Finalize code for the selected control method in the supervisory control program. Implement threading if you have chosen to do so.	Pending
			1. Integrate Encoders into project supervisor	Pending
			2. Integrate PID control	Pending
			3. Intergrate Joystick/ArrowKey control ..... Create thread	Pending
			4. Test and verify functionality	Pending
		<b>C</b>	Integrate any environmental sensors onto the board, if you have decided to do so for bonus marks.	Pending
			1. Pick desired sensors to add	Pending
			2. Create protoboard/PCB for signal conditioning circuit	Pending
			3. Mount enironmental sensors to the robot	Pending
			4. Test and verify functionality of sensors	Pending
28-Oct-16	Final Integration and Testing	<b>A</b>	Integrate the major system modules: <i>Supervisor, Linux Box, and Platform Controller</i> . Establish and confirm reliable communication between all modules.	Pending
		<b>B</b>	Write code to incorporate any environmental sensor functionality in both the Supervisor and the Platform, if any are mounted to the board.	Pending
04-Nov-16	Final Integration and Testing	<b>A</b>	Verify and validate complete system functionality.	Pending
		<b>B</b>	Complete any missed or overdue tasks.	Pending
